California Department of Food and Agriculture

Agricultural Commissioners' Crop Reports

Contra Costa County

2005-2009

California County Agricultural Commissioners' Reports from the California Department of Food and Agriculture. This collection consists of annual crop and livestock data from each of the 58 California Counties. The collection covers 1915-1981; digitization of the rest of the collection is forthcoming.

This digitization project was funded by the Giannini Foundation of Agricultural Economics, <http://giannini.ucop.edu/>.

The work was completed by the staff of the Giannini Foundation Library, University of California, Berkeley, <http://are.berkeley.edu/library/>. **Please contact the Library to consult the originals.**

Live Pests

A & Q rated pests	79
Glassy-winged Sharpshooter	5
Other weed pests	10
Other pests	4

“A” and “Q” Rated Pests

Pests vary as to the level of potential harm they can do, so it is necessary to have a rating system to represent the statewide importance of the pest to the agricultural, horticultural, forestry, environmental, and public health interests of California. The rating of a pest also determines what action is taken when it is found, such as: quarantines, eradication, rejection, control, cleanliness standards, holding, inspection, and the establishment of control districts. Of special interest are pests that are rated “A” or “Q”. These organisms have the potential to cause serious harm and require enforcement action when they are found. “A” rated pests, such as the Mediterranean Fruit Fly, are known to cause serious harm. “Q” rated pests are those that are suspected to cause serious harm but their status is uncertain because of incomplete information about the species.

Contra Costa County regularly intercepts many of these types of pests in quarantine inspections. The following were intercepted during inspections in 2005.

	<i>Rating</i>	<i>Rejections</i>
ANTS		
Technomyrmex albipes / White-footed Ant	Q	13
Pheidole megacephala / Bigheaded Ant	Q	6
Anoplolepis longipes / Longlegged Ant	Q	2
Other ant species	Q	4
SCALES		
Pseudaulacaspis cockerelli / Magnolia White Scale	A	7
Pseudaulacaspis pentagona / White Peach Scale	A	3
Milviscutulus mangiferae / Mango Shield Scale	Q	3
Pinnaspis uniloba/Unilobe Scale	Q	1
Other scale species	Q	4
MEALYBUGS		
Pseudococcus jackbeardsleyi/ Jack Beardsley Mealybug	A	1
Maconellicoccus hirsutus / Pink Hibiscus Mealybug	A	1
Planococcus minor/Passionvine Mealybug	Q	2
Other mealybug species	Q	4
WHITEFLIES		
Aleurodicus dispersus / Spiraling Whitefly	Q	3
OTHER INSECTS, MITES, & MOLLUSCS		
Kallitaxila granulata / Planthopper	Q	2
Cinara cedri/Aphid	Q	2
Stephanitis pyrioides/Azalea Lacebug	Q	1
Grasshopper / Katydid species	Q	3
Other Coleoptera species	Q	1
Other Homoptera species	Q	2
Other Lepidoptera species	Q	1
Mite species	Q	2
WEEDS		
Sesbania punicea/Scarlet Wisteria Tree	Q	2
Panicum virgatum/Switchgrass	Q	1
Cuscuta japonica/Giant Dodder	Q	1
Other weed species	Q	1
PLANT DISEASES		
Phytophthora ramorum / Sudden Oak Death	Q	6

“A” and “Q” Rated Pests

Pests vary as to the level of potential harm they can do, so it is necessary to have a rating system to represent the statewide importance of the pest to the agricultural, horticultural, forestry, environmental, and public health interests of California. The rating of a pest also determines what action is taken when it is found, such as: quarantines, eradication, rejection, control, cleanliness standards, holding, inspection, and the establishment of control districts. Of special interest are pests that are rated “A” or “Q”. These organisms have the potential to cause serious harm and require enforcement action when they are found. “A” rated pests, such as the Mediterranean Fruit Fly, are known to cause serious harm. “Q” rated pests are those that are suspected to cause serious harm but their status is uncertain because of incomplete information about the species.

Contra Costa County

2007 Annual Crop Report

When A Serious Exotic Pest Has Been Found: What's The Next Step?

As many people know, California has a pest detection program to find exotic plant pests before they grow into infestations costing hundreds of millions of dollars to eradicate. If not eradicated, these pests could cause the loss of foreign and domestic markets for California produce, serious harm to native plants, increased use of pesticides, and reduced yield and quality of California fruits, vegetables, and nursery products. But very few people know just what happens when a serious pest has been found.

The first step in the process consists of a delimitation project to find out the size of the infestation. For insects, this is usually done with detection traps. The traps may be baited with pheromones, a chemical perfume that attracts the male insect, or with a food lure to attract both males and females. During some insect delimitations, up to 1,000 traps per square mile may be used. For weed and disease pests, the delimitation step is much harder. It is necessary to physically survey the area or rely on reports from the public in order to find infestation sites. During a plant disease delimitation, samples from infected plants must be cultured in order to get a positive identification.

It is important to prevent the pest from spreading any further, so infested areas will be placed under quarantine immediately. The quarantine will control the movement of fruits, vegetables, nursery plants etc. that could carry the pest into uninfested areas. Often, additional items, such as soil, firewood, and harvest equipment, will also be restricted because life stages of the pest may hide in them.

The next step is to try to reduce and/or eradicate the pest in the infested areas. The most direct method to do this is to remove something the pest needs in order to complete its life cycle. For insects, this is usually done by removing the larval food or by preventing females from laying fertile eggs. This last method has proved to be the most effective and can be done in a variety of ways. Many male insects find mates by following a trail of pheromones put out by the female. These pheromones can be synthesized and applied to an area in large amounts, keeping the males from tracking the females. Another way to prevent female insects from laying fertile eggs is to release a large number of sterile males. The females are unlikely to find a fertile male in the crowd of sterile ones.

Physical or chemical methods can be an effective way to eradicate pests from an infested area. There are some parasitic weeds that can grow from even the tiniest fragment and must be removed along with their host plants and buried deep in a landfill. Other types of weeds are controlled by burning or by discing the soil. It may sometimes be necessary to use insecticides to kill insects or herbicides to kill weed pests. Biological control agents such as parasitic or predatory insects are often helpful when used together with other eradication methods. However, there are cases in which it may simply be impossible to successfully eradicate a pest.

Exotic pests threaten production agriculture, nurseries, and the natural environment.

Several very serious pests have been found in the San Francisco Bay Area within the last year; Mediterranean Fruit Fly (Medfly), Light Brown Apple Moth (LBAM), Japanese Dodder (a parasitic weed), Red Sesbania (a weed of riparian areas), and Sudden Oak Death (a plant disease). All are considered to be very serious threats because they have the potential to cause severe harm to both agriculture and the environment.

Mediterranean Fruit Fly (Medfly):

What is it: a fly that attacks over 260 types of fruits and vegetables. Medfly is a short, squat fly about 1/4 inches long that lays its eggs under the skin of fruits and vegetables. The larvae tunnel through the fruit as they feed and decay organisms enter, leaving the interior a rotten mass unfit for human consumption. Medfly is native to Africa, but has spread to other parts of the world including the Mediterranean, southern Europe, Australia, the Caribbean, South America, the New World tropics, and Hawaii.

Where is it in the Bay Area and how did it get here: in fall 2007, infestations were found in Dixon (Solano County) and San Jose (Santa Clara County). They probably were started when larvae infested fruit was brought back from Mexico, Hawaii, or some other vacation destination. The USDA Smuggling Interdiction Team has been investigating to identify the persons responsible for these two infestations.

What is being done about it: as of the end of 2007, Dixon had a quarantine covering 114 square miles and delimitation trapping over 90 square miles. In San Jose, the quarantine area was 75 square miles and the delimitation area was 81 square miles. In areas where Medfly larvae have been found, fruit has been stripped from host trees to remove larval food and ground sprays have been applied to kill adult flies. Both the Dixon and San Jose areas have had releases of sterile male Medflies that will continue twice a week throughout several life cycle's time. If no more wild Medflies are found, the quarantines could be lifted sometime in late 2008 or early 2009.

Light Brown Apple Moth (LBAM):

What is it: a moth that attacks over 2,000 types of agricultural, landscape and native plants. Adults are light brown and about 3/8 inches long. The larvae are green in color with a brown head and typically stick or roll leaves and buds together with silk webbing to make shelters. LBAM is native to Australia, but has spread to Hawaii, New Zealand, and Great Britain.

Where is it in the Bay Area and how did it get here: in early 2007, LBAM was first discovered in Alameda

Mediterranean Fruit Fly: (from left to right) adult fly, larvae, locations in the San Francisco Bay Area where it has been found in 2007.

County. By December 2007, it had been found in all of the Bay Area counties except Sonoma. LBAM probably was introduced into California in infested nursery stock from Australia.

What is being done about it: as of December 2007, there were areas under quarantine for LBAM in seven of the nine Bay Area counties (the quarantine in Napa County was lifted in December 2007). Ground applications of *B. t.*, a biocontrol agent, have been made to treat small, isolated infestations in Contra Costa and Napa Counties. Other small infestations in Contra Costa, Napa, Alameda, Santa Clara, and Solano Counties have been treated using pheromone impregnated twist ties. In some of these areas, there have been no more LBAM life stages found and the quarantines have been lifted. There are plans to apply LBAM pheromones by air in some parts of the Bay Area starting in late summer 2008. For the future, it may be possible to develop a sterile male release program for LBAM similar to the one used for Medfly.

Light Brown Apple Moth: (from left to right) adult male, larvae, locations where it had been found in the Bay Area in 2007.

Japanese Dodder:

What is it: a weed from Asia that looks like yellow-green or orange spaghetti. Japanese Dodder is a rapidly growing (up to six inches per day) parasitic vine capable of feeding on a wide range of landscape, crop, and native plants. It produces modified roots that take water and nutrients from its host, eventually causing weakness and death. Japanese Dodder's seeds can remain viable in the soil for up to 30 years and even tiny fragments of the plant carried by wind, water, or animals can infect any other plants they contact.

Where is it in the Bay Area and how did it get here: as of December 2007, Japanese Dodder had been found at over 70 properties in Alameda, Contra Costa, and Solano Counties. This

Japanese Dodder: (from left to right) growth on a landscape plant, vine strands, locations where it has been found in the Bay Area in 2007.

number will likely increase as surveys and public education continue. Both the seeds and strands are thought in Asia to have medicinal uses and it may first have been introduced into California as seeds in herbal supplements. In some areas, Japanese Dodder is probably being intentionally grown.

What is being done about it: the only way to control Japanese Dodder is to physically remove it along with its host plant and bury it in a landfill. This means having to cut out and dispose of plants ranging in size from small weeds to huge trees. USDA has stepped up efforts to inspect herbal medicine shipments that could contain Japanese Dodder seeds. In spite of U.S. import regulations requiring that the seeds in these herbal remedies be sterilized, viable seeds have often been found.

Red Sesbania:

What is it: a poisonous woody shrub from southern South America that grows up to fifteen feet tall with a trunk diameter of up to six inches. Each plant matures rapidly, producing bright red flowers and hundreds of seed pods that float downstream. Red Sesbania forms dense thickets along rivers and creeks, displacing native plants needed by wildlife for food and cover. The dense clusters prevent access to rivers, block waterways, and can increase bank erosion and flooding.

Red Sesbania: (from left to right) growth in a wetland, flowers, locations where it has been found in the Bay Area in 2007.

Where is it in the Bay Area and how did it get here: as of December 2007, Red Sesbania has been found growing in wetland areas in central and northern Contra Costa County and also near Santa Rosa in Sonoma County. It will probably be found in other areas in the Bay Area as surveys continue. Red Sesbania was introduced into California as an ornamental plant because of its brightly colored flowers and may be found planted in older gardens.

What is being done about it: Red Sesbania is removed by hand-pulling smaller plants and cutting down larger ones together with treating the stumps to prevent resprouting. Seed pods are collected, bagged, and buried in a landfill. Since Red Sesbania is considered a noxious weed, it is illegal to sell it or even bring it into California. In spite of this, it is still sometimes found for sale in nurseries.

Sudden Oak Death (SOD):

What is it: a fungal disease that infects over 100 kinds of ornamental and native plants. Symptoms range from leaf spots, seeping bark cankers, and twig dieback, to the sudden death of an entire tree. SOD is thought to be

spread in forests by spores carried in rainwater and soil. When conditions are cool and moist, spores may also be blown by the wind. SOD has caused widespread dieback of several tree species in forests in California and Oregon as well as affecting many other types of plants.

Where is it in the Bay Area and how did it get here: SOD has been found in all nine Bay Area Counties, primarily in coastal regions and inland valleys that receive cooling from fog. SOD was first identified on rhododendrons in Europe and was probably introduced into California on infected nursery stock.

Sudden Oak Death: (left to right) leaf spotting symptoms, tree death in a forest, locations where it has been found in the Bay Area.

What is being done about it: in wild lands and urban areas, there are no physical, chemical, or biological control methods known for SOD. Some nurseries have been able to control the disease within their growing grounds using a combination of sanitation, fungicides, and the culling of any plants with SOD symptoms. All nine Bay Area Counties are currently under quarantine to restrict the movement of nursery stock, wood, soil, green waste, etc. that might carry the disease or its spores to new areas. Nurseries inside the quarantined areas must be under a compliance agreement in order to ship host plants to non-infested areas. The compliance agreement includes visual inspections of shipments and an annual inspection where host plants are sampled and cultured for SOD.

Infestations of exotic pests are a serious concern to both California and to the Federal Government. Exotic plant pests that became established in California could spread into other states and threaten their agriculture industries and the environment. California and the rest of the nation could face enormous losses in export markets as a result of quarantines established by our international trading partners against exotic plant pests, diseases, and weeds. There already have been specific quarantines for Medfly, LBAM, and SOD placed on the Bay Area Counties that restrict the ability of local growers to market and ship their agricultural commodities.

When exotic plant pest infestations are found, it is important to respond as soon as possible. The longer a pest population exists, the greater the chance it will spread and become permanently established. Small populations can be controlled and eradicated more successfully than large ones. Too much delay only allows the problem to grow out of control.

* Contra Costa County has two canine detection teams. These values represent finds in Contra Costa County only.

“A” and “Q” Rated Pests

Pests vary as to the level of potential harm they can do, so it is necessary to have a rating system to represent the statewide importance of the pest. Of special interest are pests that are rated “A” or “Q”. These organisms have the potential to cause serious harm and require enforcement action when they are found. “A” rated pests, such as the Mediterranean Fruit Fly, are known to cause serious harm. “Q” rated pests are those that are suspected to cause serious harm but their status is uncertain because of incomplete information about the species.

photo courtesy of the Muir Historical Site

On the Cover: This year's cover of the Contra Costa County 2008 Annual Crop Report features some early wine labels from the Martinez area. Prior to Prohibition, Martinez was the home to many wineries. As the photo above of the John Muir house in 1910 shows, there was considerable grape acreage planted in and around Martinez.

* Contra Costa County has two canine detection teams that work in the Bay Area. The canine program values represent finds not marked as containing plant material in Contra Costa County only.

“A” and “Q” Rated Pests

Pests vary as to the level of potential harm they can do, so it is necessary to have a rating system to represent the statewide importance of the pest. Of special interest are pests that are rated “A” or “Q”. These organisms have the potential to cause serious harm and require enforcement action when they are found. “A” rated pests, such as the Mediterranean Fruit Fly, are known to cause serious harm. “Q” rated pests are those that are suspected to cause serious harm but their status is uncertain because of incomplete information about the species.

CONTRA COSTA

COUNTY, Calif.

Agricultural Commissioner 2009 ANNUAL CROP REPORT

MAY 25 2010
LANNING FOUNDATION OF
CALIFORNIA AGRICULTURE

To: A. G. KAWAMURA, SECRETARY
CALIFORNIA DEPARTMENT OF FOOD AND AGRICULTURE
and
THE HONORABLE BOARD OF SUPERVISORS

I am pleased to submit the 2009 Annual Crop and Livestock Report for Contra Costa County in accordance with the provisions of Section 2279 and 2272 of the California Food and Agricultural Code. This report includes information on Organic Farming and Biological Control activities in our county.

The total gross value of agricultural crops and products in 2009 was \$64,423,280, down \$6,810,340 from 2008. The value of the Vegetable and Seed Crop category increased sharply as the harvested acres and price per ton of sweet corn, processing tomatoes, and crops in the miscellaneous vegetable and seed crop category improved. The continuation of drought conditions in 2009 left rangeland in poor condition, causing cattle producers to keep herd size low. Apple production decreased to low levels and had to be included in the miscellaneous fruit and nut crop category. However, olive production increased to the point that the crop could be removed from the miscellaneous fruit and nut crop category and listed separately.

Hay prices dropped sharply in 2009 as reduced demand due to cuts in dairy production in California led to a glut in supplies of both grain hay and alfalfa. Low wheat prices plus poor grain development due to the lack of winter rain led to growers either harvesting their fields as wheat hay or not harvesting them at all. Low prices for safflower and field crops used for livestock feed reduced both the harvested acreage and value of the miscellaneous field crop category. Walnut acreage decreased due to development. Because of the loss or reduced operations of producers of bedding plants, herbaceous perennials, and miscellaneous nursery crops during 2009, there were decreases in those crop categories.

Several crop categories exceeded \$1 million in value. These categories in decreasing order include sweet corn, tomatoes, grapes, cattle and calves, field corn, rangeland pasture, cherries, alfalfa, apricots, beans, walnuts, herbaceous perennials, and irrigated pasture.

It should be emphasized the values stated in this report are gross receipts and do not include the cost of production, transportation, or marketing of the products. The economic benefit of agricultural production is generally thought to be about three times the gross production value.

I wish to thank the many individuals and organizations who supplied us with the information to complete this report. Their cooperation is truly appreciated. I also would like to thank Nancy Niemeyer and the rest of my staff for their diligent work in obtaining, compiling, and coordinating their efforts to put together our annual report.

Respectfully submitted,

Vincent L. Guise

Bart (handler: Mariah Slusser)

On the Cover: sweet corn production - (left top to bottom) plowing the field, beds ready for planting, harvest, packing, roasted corn ready to eat; and (right) a field before harvest.

Above: Growing sweet corn requires careful monitoring and pest management in order to control the many insects, weeds, and diseases that attack the crop. Some of these pests are shown above: cutworms, grasshoppers, corn earworm, bindweed, purslane, johnson grass, root rot, and corn smut.
