Measuring Economic Well-Being of Rural Canadians Using Income
Indicators

Carlo Rupnik, Margaret Thompson-James and Ray D. Bollman
Statistics Canada

March 2001

Catalogue no. 21-601-MIE01045

The responsibility for the analysis and interpretation of the data is that of the authors and not of Statistics Canada.

Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

Measuring Economic Well-Being of Rural Canadians Using Income Indicators

Carlo Rupnik, Margaret Thompson-James and Ray D. Bollman

Introduction

By broadening a region's economy, the increase in population and the improved access to markets can lead to improved economic prosperity for several reasons, including increasing consumer demand, economies of scale, economic flexibility, labour force productivity, savings, entrepreneurship, and opportunities for creating new knowledge and technology. These factors can significantly impact a region's economic well-being.

Lower populations and less accessibility to markets in rural areas may impose challenges to their economic prosperity. Improving the well-being of rural Canadians is one of the stated objectives of federal rural policy (Mitchell, 2000). There are many economic and non-economic components of "well-being". The objective of this paper is to provide an overview of the economic well-being of rural Canadians using a variety of income indicators. Incomes can be described in terms of levels and distribution. Levels refer to average and median incomes. Distribution refers to how incomes are distributed in an area in terms of the proportion of families with low incomes, the degree of income inequality, and through government transfers.

Income indicators

The following indicators will be used to describe the income levels of rural Canadians:

Levels

- average and median incomes for families and individuals, national and provincial;

Distribution

- the proportion of families with income below the low income cut-offs (LICOs);
- the proportion of families with income below the low income measures (LIMs);
- measures of the degree of income inequality (the Gini coefficient);
- the correlation of in-migration to a community with the measured incidence of low income in the community; and
- governmental impact on incomes through transfers and taxes.

Most of the analysis will be presented at the national level, with the exception of incomes, which will be presented at the provincial level as well.

Definitions

Most of the income data reported in this paper has been tabulated from the former Survey of Consumer Finances (SCF). This survey has been replaced with the Survey of Labour Income Dynamics. The sample for the SCF was drawn from the Labour Force Survey (LFS) sampling frame. The target population for the survey is all families and individuals residing in Canada, with the exception of people in the territories, residents of institutions, and people living on reserves.

The definition of “rural” in the LFS is (generally) individuals living outside centres of 1,000 or more and who live outside the commuting zones of urban centres of 10,000 or more. Urban refers to those areas that are not rural.

“Family” is defined as a group of individuals (2 or more) sharing a common dwelling unit and related by blood, marriage or adoption. Thus, all relatives living together are considered to comprise one family whatever the degree of family relationship. This definition of family is the “economic family” definition.

The term “individual” in this paper refers to any person 15 years of age and over who received some money income during the reference year.

Other terms will be defined as they arise in the paper.

Average and median incomes for families

Incomes are lower in rural areas. For the past three decades, rural families and individuals have had the lowest average and median incomes and the most populous areas (100,000 or more) have had the highest incomes.

In 1997, the average income for families living in rural areas was \$48,850 while in areas with a population of 100,000 or more the average family income was \$59,920 (Figure 1).

Figure 1

Rural families have the lowest average incomes

Source : Statistics Canada. Income Distribution by Size in Canada. (Cat. No. 13-207).

Incomes reached lows near the end of the recession in 1983. Through the eighties incomes recovered to pre-recession highs. In the nineties incomes declined for urban areas but remained flat for rural areas. As a result, by 1997 urban area incomes had not increased much from recession lows, while rural area incomes remained near pre-recession highs. This also resulted in narrowing the gap between rural and urban incomes.

The income gap between rural areas and smaller urban centres has been falling the most. Since 1990, the average income gap between rural areas and cities under 15,000 population fell by 58 percent. Even against the 100,000 plus population areas, the rural-urban income gap has fallen by 20 percent. By 1997, the average income for a rural family was only \$359 below that of a family living in an urban area with a population less than 30,000 (Figure 2).

Figure 2

Average income gap between rural and urban areas for families

Source : Statistics Canada. Income Distribution by Size in Canada. (Cat. No. 13-207).

Similar patterns are seen for median family incomes. Rural families have lower median incomes. In 1997, the median income for families living in rural areas was \$42,470 while in areas with a population of 100,000 or more the median family income was \$53,101 (Figure 3).

Figure 3

Rural families have the lowest median incomes

Source: Statistics Canada. Survey of Consumer Finances.

Since 1990, the median income gap between rural areas and urban areas has decreased for each urbanisation class. The gap between rural areas and smaller towns (under 15,000 population) has fallen the most. This gap in median income decreased by 79 percent. Against the 100,000 and over population class, the median income gap has decreased by 19 percent. In 1997, the median income for a rural family was only \$555 below that of a family living in an urban area with a population less than 30,000 (Figure 4).

Figure 4

Median income gap between rural and urban areas for families

Source: Statistics Canada. Income Distribution by Size in Canada (Cat. No. 13-207).

Average and median incomes: individuals with income

Rural individuals also lag their urban counterparts in terms of average and median incomes.

As with family incomes, individual incomes are higher in larger cities as rural individuals have the lowest incomes and individuals in the most populous areas (100,000 or more) have the highest. Also, similar to the case for family incomes, the income gap between rural and urban individuals has been declining in the nineties.

In 1997, the average income for an individual living in rural areas was \$22,214 while in areas with a population of 100,000 or more the average individual income was \$27,029 (Figure 5).

Figure 5

Rural individuals have the lowest average incomes

Source: Statistics Canada. Income Distributions by Size in Canada (Cat. No. 13-207).

Since 1990, the average income gap between rural individuals and urban individuals has fallen against each urbanisation class. The gap between rural areas and the least populous urban areas has been falling the most. Against the less than 15,000 population class, the average income gap fell by 37 percent. Against the 100,000 plus population class, the gap has fallen by 16 percent (Figure 6).

Figure 6

Source: Statistics Canada. Income Distribution by Size in Canada. (Cat. No. 13-207).

Similar patterns are seen for individual median incomes. In 1997, the median income for an individual living in rural areas was \$16,811 while in areas with a population of 100,000 or more the median individual income was \$21,613 (Figure 7).

Figure 7

Rural individuals have the lowest median incomes

Source: Statistics Canada. Income Distribution by Size in Canada. (Cat. No. 13-207).

As with the average income of individuals, since 1990 the median income gap between rural individuals and individuals in each urbanisation class has been decreasing. The difference between individual median incomes in rural areas and in smaller cities has been decreasing the most. Against the 15,000 to 30,000 population areas the gap has decreased by 48 percent. The gap with the less than 15,000 population areas decreased by 47 percent. Against the 100,000 plus population areas the gap has decreased by 15 percent (Figure 8).

Figure 8

Source: Statistics Canada. Income Distribution by Size in Canada. (Cat. No. 13-207).

To summarise the national picture

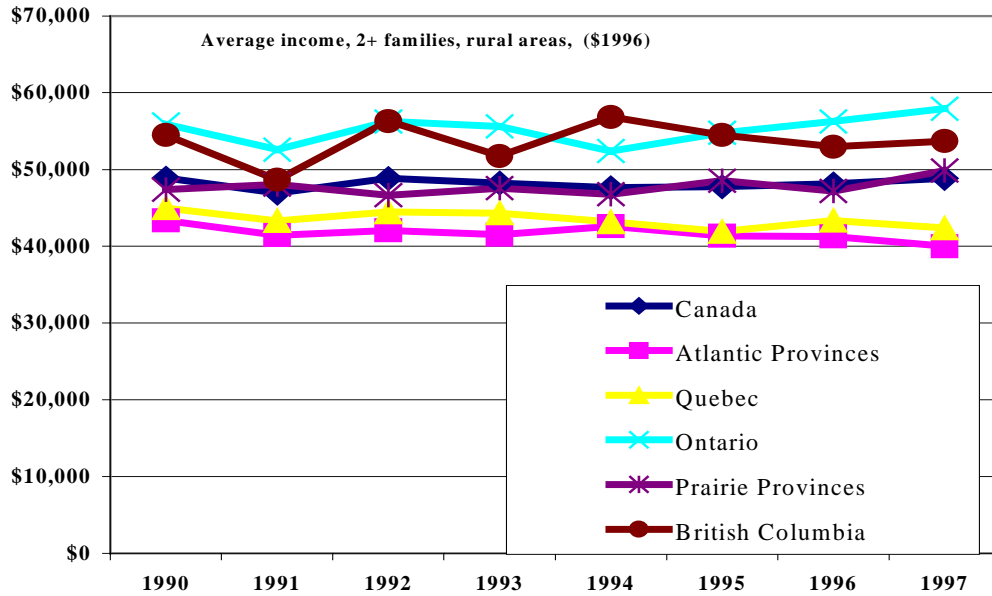

Overall, the data shows that incomes have not changed much since the early 1980s. Significant average and median income gaps remain between rural and urban areas for both individuals and families. The gap is larger when comparing rural areas to larger urban areas, reflecting that incomes are higher in larger cities. However, since 1990, because urban incomes have fallen while rural incomes have remained flat, all of these rural and income gaps have been declining. The rate of decline in the gap has been largest between the least populous urban areas.

Provincial trends

Reflecting the national trend, provincial rural average family incomes have generally remained flat through the nineties. Rural families in Ontario and British Columbia have the highest average incomes while rural families in the Atlantic Provinces and Quebec have the lowest average incomes (Figure 9).

Figure 9

**Rural families in Ontario and British Columbia
have the highest average incomes**

Source: Statistics Canada. Survey of Consumer Finances.

In addition to having the highest incomes amongst rural areas in Canada, rural family incomes in Ontario and British Columbia are closer to the family incomes in the large cities in their respective provinces, compared to the situation of rural families in other regions. In recent years, rural families in Quebec have been the furthest behind the income levels of families in the larger cities in Quebec.

Rural family incomes in Ontario and British Columbia have generally been between 10 to 15 percent lower than family incomes in areas with a population of 100,000 or more within their province. In contrast, rural family incomes in Quebec are approximately 20 percent lower compared to the urban areas with 100,000 or more population in Quebec (Figure 10).

Figure 10

Rural families in Ontario and British Columbia have the closest incomes to families in cities with 100,000 or more population in their province

Source: Statistics Canada. Survey of Consumer Finances.

A provincial analysis of median family income and average and median individual incomes yields similar results as above.

Low income cut-offs

Low income cut-offs (LICOs) reflect an income level where families are substantially worse off in the sense that they have to spend a greater proportion of their income on necessities than the average family of a similar size. The LICO has been recalculated with data for each Family Expenditure Survey during the 1980s and 1990s. The average spending on necessities in that base year drives the calculation of the cut-offs.

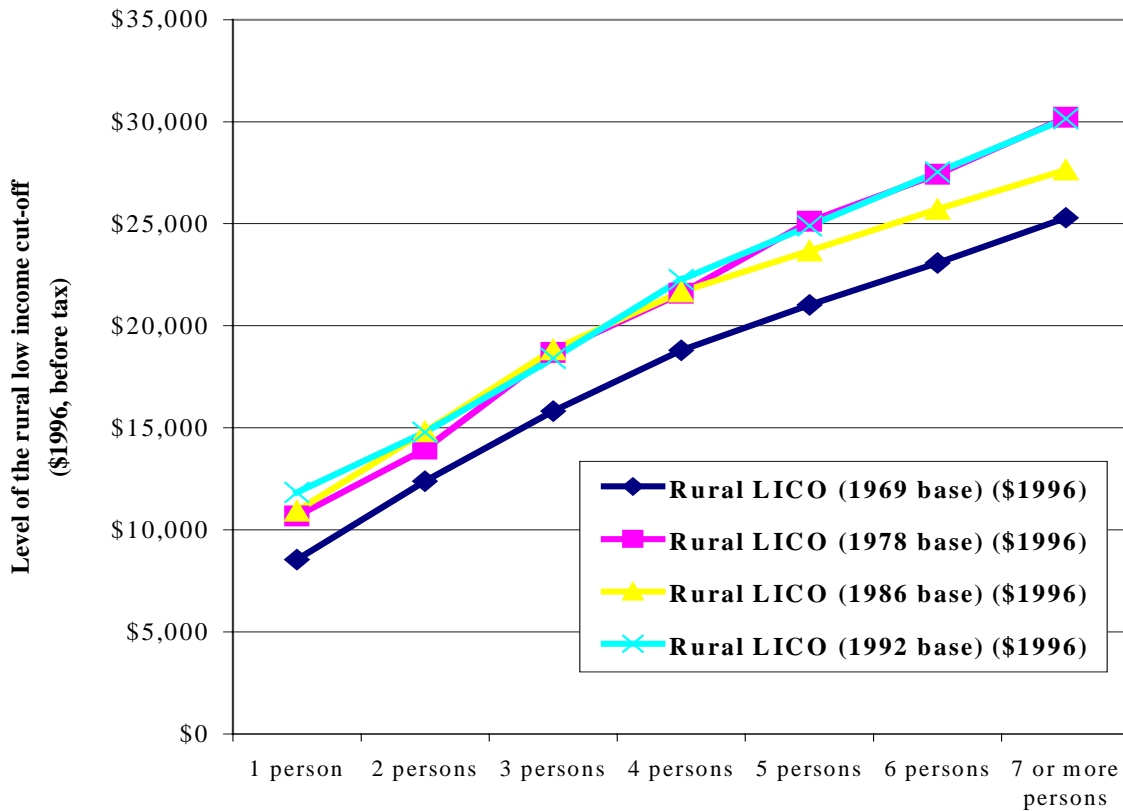

The LICOs calculated for rural areas are similar using either 1978, 1986 or 1992 as base years. Only the low income cut-off defined for 1969 has a substantively lower cut-off level (Figure 11).

Low income cut-offs (LICOs) are established using data from Statistics Canada's Family Expenditure Survey, now known as the Survey of Household Spending. They convey the income level at which a family may be in straitened circumstances because it has to spend a greater proportion of its income on necessities than the average family of similar size. Specifically, the threshold is defined as the income below which a family is likely to spend 20 percentage points more of its income on food, shelter and clothing than the average family. There are separate cut-offs for seven sizes of family – from unattached individuals to families of seven or more persons – and for five community sizes – from rural areas to urban areas with a population of more than 500,000.

To calculate the proportion of individuals with low incomes, the family size and community size are used to find the appropriate cutoff.

Figure 11

Rural LICOs are similar in 1978, 1986 and 1992

Source: Statistics Canada. Low Income Cut-offs (LICOs). (Cat. No. 13-551).

The calculated LICO levels are higher in larger cities. Families living in communities of 500,000 or more persons require the most income to be above the LICO level (i.e. to avoid “straitened circumstances” due to the higher cost of food, clothing and especially shelter (see Marshall and Bollman, 1999)). Rural areas have the lowest LICO levels for each family size (Figure 12). This indicates that rural families are better off at lower income levels in the sense that the necessities of food, clothing and especially shelter are achieved at a lower income level. This reflects the lower cost of living in rural areas.

Figure 12

Rural areas have the lowest LICO levels

The largest difference in LICO limits are between the 500,000 and over population class and the rural class. The difference in LICO limits between these two population classes ranges from \$5,290 for a single person family to \$13,473 for a family with 7 or more persons (1992 base). This means that a family with 7 or more persons living in a community with a population of 500,000 and over would require \$13,473 more income to be above the LICO level than the same sized family living in a rural area. The differences in LICO limits are similar using either 1986 or 1992 as base years (Figure 13).

Figure 13

The difference between LICO limits for the 500,000+ urbanisation class and rural areas is similar in 1986 and 1992

Source: Statistics Canada. *Low Income Cut-offs (LICOs)*. (Cat. No. 13-551).

The methodology for deriving the cut-offs for each family size essentially imposes a constant adjustment across all family size classes so that family size does not affect the proportional differences in LICO limits. The ratio of the low income cut-off for rural versus cities with 500,000 persons and over is a constant ratio across all family size classes. For each family size, rural LICO limits are approximately 31 percent below those for communities with a population of 500,000 and over (1992 base) (Figure 14).

Figure 14

The rural LICO limits are a constant proportion below the LICO limits for the 500,000+ urbanisation class

Source: Statistics Canada. *Low Income Cut-offs (LICOs)* (Cat. No. 13-551).

Low income rates give the proportion of families with income below the LICO level. This gives an indication of the economic well-being of a community in terms of the proportion of its residents who are restrained in their relative ability to purchase necessities.

Through the 1990s, within each community size low income rates have not fluctuated significantly. The rates are higher in larger cities as rural families have the lowest rates and the most populous areas (500,000 and over) have the highest incidence of low incomes. Rates for families living in rural areas remained at slightly below 10 percent while for those living in areas with a population of 500,000 and over the rates ranged from 16 to 18 percent (Figure 15).

Figure 15

Rural areas have the lowest proportion of families with low income (based on LICO)

Source: Statistics Canada. *Income Distribution by Size in Canada*. (Cat. No. 13-207)

This indicates that, economically, rural communities are better off than urban communities in the sense that a lower proportion of its residents is restrained in their relative ability to purchase necessities.

Low income measures

Low income measures (LIMs) are one alternative to low income cut-offs for measuring the size, incidence and composition of the low income population.

Low income rates give the proportion of families with income less than one-half of the median adjusted family unit income (LIM level). This gives an indication of the economic well-being of a community in terms of the proportion of its residents who have income below a low income level determined by LIM.

Through the 1990s, like the low income rates based on LICO, low income rates based on LIM have not fluctuated significantly within each community size. However, across different community sizes, LIM rates have exhibited the opposite pattern of LICO rates. Unlike LICO rates, LIM rates are higher in smaller areas as rural families have the highest rates and the most populous areas (500,000 and over) have the lowest. LIM rates for families living in rural areas were approximately 15 percent while for those living in

areas with a population of 500,000 and over the rates were approximately 12 percent (Figure 16).

The low income measure equals half of adjusted median family income, where the adjustment is made in consideration of family size. This adjustment for family size reflects the precept that family needs increase with family size. For example, a family of four needs a higher income than a family of two in order to enjoy the same standard of living. By how much must the larger family's income exceed the income of the smaller family in order for the two families to have equivalent standards of living is decided arbitrarily. Each additional adult is assumed to increase the family's needs by 40 percent of the needs of the first adult. Each child's (less than 16 years of age) needs are assumed to be 30 percent of the first adult, except in a family with only one adult, where the first child is assumed to increase the family's needs by 40 percent of the needs of the only adult.

Figure 16

Source: Statistics Canada. Survey of Consumer Finances.

This indicates that, economically, rural communities are worse off than urban communities in the sense that a higher proportion of its residents has income below a low income level determined by LIM.

The reason for this is that in the LIM methodology all families are compared to the national-level median income. Because rural people have lower incomes, rural has the highest proportion of families with income below this measure. This “low income measure” is becoming accepted as an international standard. Since it does not take account of the differences in the cost of living among urbanisation classes, this measure will show that countries with a high proportion of rural population will have a relatively high proportion of families below this “low income measure”. However, wages in rural areas are often lower because the cost of living is lower. As a result, incomes would be lower and the LIM would show a higher incidence of low income in these areas. However, the (lower) income level in areas with a lower cost of living may have the same real value as the (higher) income in a higher cost of living area. Thus, even if the real value of income were the same in these two areas, the LIM would be higher in the low income area.

It is important to note that LICO and LIM do not measure the level of poverty in Canada. The level of poverty cannot be measured because unlike concepts such as gross

domestic product or consumer prices, currently there is no consensus on how to define poverty. Relying on a well-defined methodology based on arbitrary assumptions, they measure the extent and composition of the low income population, in terms of those who are worse off than average. This does not necessarily measure poverty¹.

Gini coefficient of inequality

The Gini coefficient can be applied to incomes to describe the nature of the income distribution. It measures the degree of inequality in an income distribution. Gini coefficients can be used to compare the uniformity of income allocation across different populations over time. The Gini coefficient is constructed in such a way that it ranges in value from 0 to 1 where higher values are associated with greater income inequality.

Gini coefficients are higher in larger cities. Since the 1980s, rural areas had the lowest degrees of income inequality while areas with a population of 100,000 and over had the highest (Figure 17). This indicates that incomes are more equally distributed within rural areas so that those earning lower incomes are not as far behind higher income earners compared to the situation within more populous areas. In this sense, the economic well-being of rural areas is “better” than in urban areas.

The Gini coefficient, as applied to incomes, measures the degree of inequality in an income distribution. The Gini coefficient is constructed in such a way that it ranges in value from 0 to 1 where higher values are associated with greater income inequality. A value of zero indicates income is equally divided among the population with all units receiving exactly the same amount of income. At the opposite extreme, a Gini coefficient of 1 denotes a perfectly unequal distribution where one unit possesses all of the income in the economy. A decrease in the value of the Gini coefficient can be interpreted as reflecting a decrease in inequality, and vice versa. A difference of 0.01 or more between two Gini coefficients is considered statistically significant.

¹ Further discussions regarding issues pertaining to the measurement of poverty can be found in Wolfson (1989) and Fellegi (1997).

Figure 17

Rural areas have a lower degree of income inequality

Source: Statistics Canada. Survey of Consumer Finances.

Correlation of migration into a community and the measured incidence of low income

The level of living often acts as a motivating factor affecting migration. Typically, people have disincentives to migrate into an area with a perceived low level of living. If low income rates reflect a low level of living, then it would be expected that migration rates are lower into areas with a higher proportion of individuals with low incomes. In this way, depending on the degree of labour mobility, economic viability - as measured by income levels - can reduce migration into one area and increase it into another.

Migration patterns in Canada have adhered well to theory, indicating a mobile labour force. A case in point is the population exchanges that have occurred between Eastern and Western Canada. Since the early 1970s migration into Alberta increased substantially as a result of increased exploration and development in the oil fields. As the world oil situation deteriorated in the mid 1980s, however, the rate of migration into Alberta began to fall. Since that time Alberta has seen renewed strength in migration rates in response to improving economic conditions resulting from recovering oil prices.

There are countless cases in Canada where areas with higher incomes have seen increased migration while fewer people move into areas with lower incomes.

Here we consider the gross rate of migration into a community of persons 25 to 29 years of age and we look to see if this migration rate is higher or lower into communities with a higher proportion of families with low incomes. If our measure(s) of the incidence of low incomes are indicating “less prosperous” or “poorer” communities, we would expect the rate of migration into these communities to be less. In fact, whether we use LICO or LIM as the measure of the incidence of low incomes, we find a lower rate of migration into communities with a higher incidence of low income families (Figures 18 and 19). Fewer people move into areas with higher low income rates indicating that measured low income rates are a good indication of a low level of living.

Figure 18

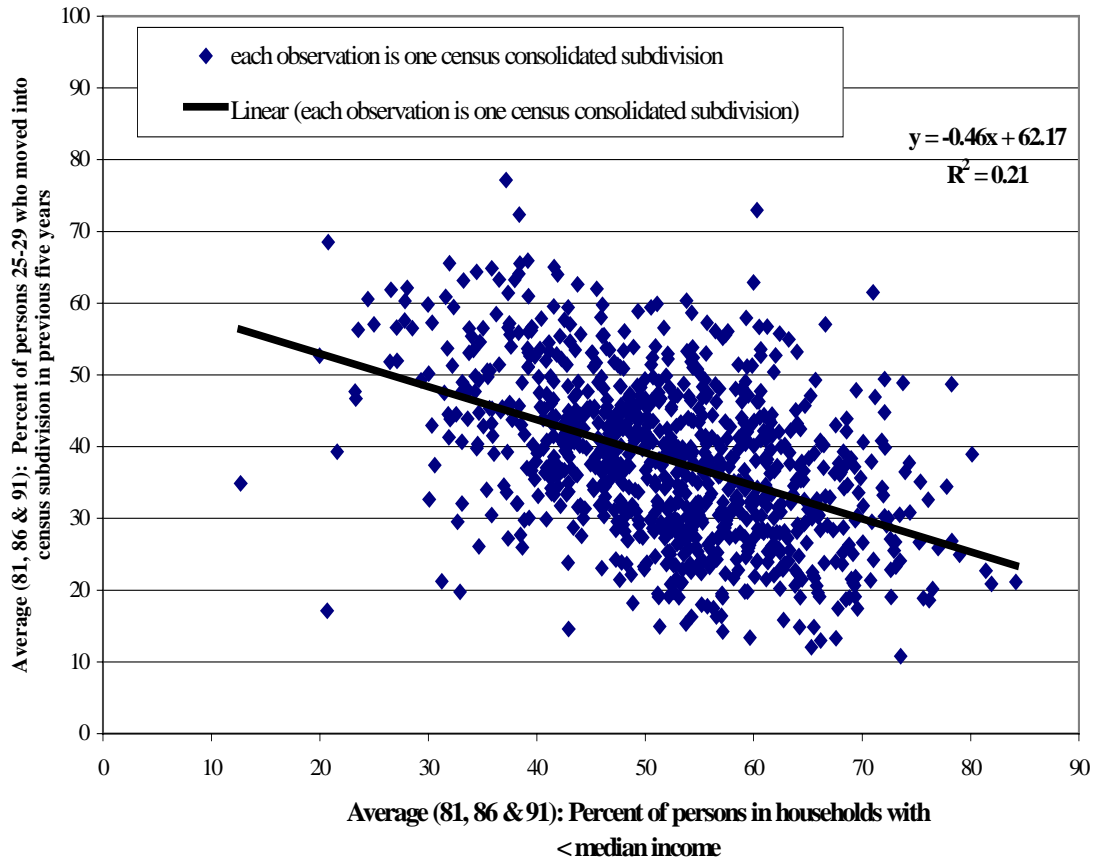

**In-migration of persons 25-29 is NEGATIVELY correlated
with community incidence of low income, based on LICO
(for communities in predominantly rural regions)**

Source : Statistics Canada. Census of Population, 1981, 1986 and 1991.

Figure 19

In-migration of persons 25-29 is NEGATIVELY correlated with community incidence of low income, based on LIM for communities in predominantly rural regions

Source: Statistics Canada. Census of Population, 1981, 1986 and 1991.

It should be noted that the degree of correlation is weak but it appears to indicate the general pattern. For any level of the measure of the incidence of low income, there is a wide range (from 10 to 70 percent) in the proportion of individuals aged 25 to 29 that moved into the communities in the previous five years. The highest correlation was found for the individuals aged 25 to 29 – the correlation for other age groups was lower (graphs not shown).

Governmental impact on incomes through transfers and taxes

Government transfers and taxes affect incomes. Receiving more transfers than paying in taxes increases income.

There are different ways to measure the difference between transfers received and taxes paid. In terms of the transfers received and taxes paid as a proportion of total income for the average person, rural and small urban area residents had both one of the

highest levels of transfer income and lowest average tax loads². In all community sizes, the average person receives more transfers than one pays in taxes (Figure 20).

Figure 20

The average rural and small city person receives more in transfers than s/he pays in taxes and the difference is larger than in metro centres

Source: Statistics Canada. Social Policy Simulation Data Base / Model.

In terms of the transfers received and taxes paid as a proportion of aggregate income in a region, rural and small urban areas had both one of the highest levels of transfer income and lowest tax loads relative to their aggregate income (Figure 21).

² This section uses data from the Statistics Canada Social Policy Simulation Database / Model and provides an update of Murphy (1992). Transfers refer to cash transfers to households such as unemployment insurance, social assistance, and through the Old Age Security program. Taxes refer to personal income taxes, sales taxes, and payroll taxes that are borne directly by households.

Figure 21

The rural and small city population pays more in taxes than it receives in transfers but the gap is smaller than in metro areas

Source: Statistics Canada. Social Policy Simulation Database / Model.

Interestingly, in all community sizes, total taxes exceeded total transfers even though it was previously seen that the average person receives more transfers than one pays in taxes (Figure 20). Due to an income distribution with a small proportion of individuals with high income coupled with a progressive income tax system, more total taxes are collected than are paid in transfers. However, the average person (in the middle of the income distribution) receives more transfers than is paid in taxes.

On average, rural individuals tend to receive relatively more transfers, at least in part because their unemployment rates are higher, there is a higher proportion of children (and thus rural residents receive more from the child tax credit) and there is a higher proportion of retired people which receive Canada and Québec Pension Plan benefits. As well, on average, rural individuals pay lower taxes because their incomes are lower.

Summary

Differences in population size and access to markets, among other things, have led to differences in the economic well-being between rural and urban residents.

Collectively, the income indicators show inconclusive evidence regarding the relative economic well-being of rural residents. Some indicators have shown that rural residents are worse off. Although recently the income differences have been declining, more so with smaller urban areas, average and median income levels, for both families and individuals, are lower in rural areas. Incomes are lowest amongst rural families in the Atlantic Provinces and Québec. In addition, the incidence of low incomes, as measured by the 'low income measure' (LIM) is higher in rural areas.

In contrast, some indicators have shown that rural residents are better off. Opposing the LIM results, based on LICO data, which makes adjustments for the cost of living across urbanisation classes, the incidence of low incomes is lower in rural areas. Furthermore, the GINI coefficients show that income is more equally distributed within rural areas. Finally, rural areas have a relatively higher level of transfer income and a lower average tax load.

The mixed evidence elicited from the indicators makes determining a conclusion regarding the relative economic well-being of rural residents difficult. Overall, perhaps the best conclusion is that it is inconclusive, depending on the indicators used and the value attributed to them.
