Abstract

The key question of this paper is why farmers in Kosovo leave land fallow when the total land of their farms is rather small and households are rather large. In order to elicit some barriers to land utilisation in Kosovo, the paper is based on a comprehensive survey carried out in 2005 investigating agricultural households' perceptions of production and market conditions, and employs several households and farm characteristics to empirically approximate the significance of different factors for leaving land fallow and not using it for production purposes. Three different econometric models are used expected to fit the data distribution.

All estimated model specifications show a statistical significance at a satisfactory level and no severe signs of misspecification. The main determinants of the share of land left fallow by farmers in Kosovo are economic: low profitability of farming and difficulty to access inputs. The increase in incentives to farmers by improving market institutions up- and downstream is one measure which could alleviate the barriers to land use. Larger arable areas decrease the probability for fallow land. This emphasizes the need for land consolidation.

Keywords: fallow land decision, Kosovo, Tobit regression, Fractional response regression, Zero-inflated binomial regression

1. Introduction

Western Balkans incorporate several potential European Union (EU) candidate countries.¹ They are more underdeveloped and poorer in comparison to the two most recent EU Member States from the Balkans – Bulgaria and Romania. In agriculture, structural differences prevail between these countries and the EU8+2 (the New EU Member States from Central and Eastern Europe). Despite some reforms in the agricultural sector, interrupted by military conflicts, subsistence and semi-subsistence farming prevails in Western Balkans. In their Progress Reports on the Potential Candidate Countries of November 2008, the Commission of

¹ The potential candidate countries are Albania, Bosnia and Herzegovina, Kosovo, Montenegro and Serbia.

the European Communities underlined the structural weaknesses, land fragmentation and the low level of technical education of farmers as impediments to competitive agriculture (CEC, 2008). Moreover, the Progress Report on Kosovo concluded that farms are too small and lack modern technologies to compete even on the domestic market. This creates an interesting research and policy problem, namely to see how this unfavorable farm structure and lack of modern technologies impact farmers' decisions for land utilisation and production of food.

The aim of this paper is to investigate the determinants behind farmer's decisions to leave land fallow in the Western Balkans, taking Kosovo as a case study. This can shed light on the main barriers faced by farmers in the potential EU candidate countries to use their small land plots and produce food for subsistence and/or market. Thus, the key question of the paper is why farmers leave land fallow when the total land of their farms is rather small and households are rather large. It has to be noted that land has not been left fallow for the sake of long-term improvements of fertility or other agri-environmental reasons. Kosovo farmers would like to cultivate it and generate incomes but seem to be constrained by underdeveloped markets and market institutions.

In order to elicit some barriers to land utilisation in Kosovo, the paper is based on a comprehensive survey investigating agricultural households' perceptions of production and market conditions, and employs several households and farm characteristics to empirically approximate the significance of different factors for leaving land fallow and not using it for production purposes. Three different econometric models are used, that are expected to fit the data distribution.

The paper is structured as follows. The next section comprises a literature review on the potential determinants of fallowing decisions. The third section includes a brief overview of Kosovo agriculture and presents the data set used. The fourth section is devoted to modeling and analysis, whilst section five presents and discusses the results. The last section concludes.

2. Potential determinants of the decisions to leave land fallow

Fallow agricultural land means that some arable land is left uncultivated or some pasture land is kept unused. Several terms for this practice can be found in the literature: fallow land, unused land, unutilised land, idle land, abandoned land, land taken out of production. While most of the terms are interchangeable, it is understood that abandoned land is land left fallow for a long time without the intention to use it in the near future. With a different aim and different methods, researchers in several fields – agronomy, geography, environment, economics – have investigated land use decisions of farmers, including fallowing decisions. Factors influencing the decisions to leave land fallow can be grouped in five categories: agronomic, economic, human, institutional, and policy.

Agronomic factors

Fallowing some land may be part of a strategy to improve soil fertility. Leaving land uncultivated for one or more seasons help soil recovery and can result in higher crop yields (e.g. Grisley and Mwesigwa, 1994; Ravnborg and Rubiano, 2001). Besides the fertility strategy, leaving some land unused or even abandoned may be the result of bad climate and agronomic conditions in specific areas, which may discourage farmers from using certain plots. For example, Chomitz and Thomas (2003) explain that land abandonment is common in high rainfall areas in Amazonia, while Mmopelwa (1998) reports that insufficient rainfall is one reason for land fallowing in Botswana. Bamewerinde et al. (2006), Coxhead and Demeke (2004), Ravnborg and Rubiano (2001) and Wicky (1994) have shown how low soil conditions

positively influence fallowing decisions for farmers in Uganda, Philippines, Colombia and Poland respectively.

Economic factors

The assumption that farmers behave as profit-maximisers may help explain why some land is left unused. In particular, plots for which farming costs outweigh the revenue are left fallow. This may be the case for plots located in remote location, and for which the access may be too difficult or costly (e.g. Wicki, 1994; Bamewerinde et al., 2006; Gellrich and Zimmermann, 2007; Bakker and van Doorn, 2009). Fallowing may also apply to plots of low soil quality, for which improving fertility by chemical or mechanical techniques is costly (see the category of agronomic factors). Farmers may also choose to leave some land idle when it is highly fragmented: farming a small parcel of land may not be profitable. Fragmentation was, for example, put forward by Kopeva et al. (2002) as one reason explaining the amount of unused land in Bulgaria during transition, while Baudry and Thenail (2004) have observed that in France smaller fields were more often left fallow than the larger ones. Some studies also report that costly access to inputs or not enough liquidity may prevent farmers from using agricultural land (e.g. Mmopelwa, 1998; Coxhead and Demeke, 2004; and Ravnborg and Rubiano, 2001).

Farmers also trade-off between farming and having a non-farm occupation, potentially resulting in land being unused. Part-time farmers, having to split their time between on-farm and off-farm labour, may leave some land idle due to time constraint. Gellrich and Zimmermann (2007) observe that land abandonment is higher in Swiss mountainous regions characterised by a low share of full-time farmers. Wicki (1994) reports at the beginning of the transition in Poland one of the main reasons for leaving land fallow was the availability of jobs outside agriculture. Farmers may also fully abandon their farm activity and leave land fallow until the farm is taken over. Migration of rural inhabitants to cities or abroad may thus be a factor leading to land abandonment, as observed in Albania during transition (Müller and Sikor, 2006).

Human factors

The reasons why part-time farmers or farmers who migrate out of rural areas/or abroad keep their land unused instead of transferring it to another land user may be explained by non-economic factors. For example, land may be viewed as an asset with a personal or family value. This reason may also lead aged landowners to keep their land unused to bequeath to their heir or to transfer once their successor is ready.

This may also explain the widespread case of absentee landowners in the former centrally planned countries. During transition, land that was previously collectivised was restituted to former owners or their heirs, or distributed among State farm workers or citizens, depending on political decisions in different countries (see Lerman, 2001, and Giovarelli and Bledsoe, 2001). Large part of the land was restituted to the heirs living in cities and engaged in non-farming jobs. Some of these absentee landowners wanted to keep the land as an attachment to a family asset and, although, some have rented it out, some have left it abandoned. Nikodemus et al. (2005) mention such a situation in Latvia, while Hedin (2005) underlines that this might be the case for Swedes living in Sweden but having some land restituted in Estonia due to the change in country boundaries.

Institutional factors

Institutional factors, such as unclear property rights and missing land market institutions, are common in the former centrally planned countries due to the incomplete land reforms (Swinnen and Vranken, 2005; Latruffe and Le Mouél, 2006). Land reforms have taken long

periods of time due to high transaction costs, namely problems of identification (due to the removal of physical boundaries of land parcels during collectivisation or the deaths of the former owners) and the slow creation of the necessary institutions such as land registry (Latruffe et al., 2008). Uncertainty regarding land ownership and transaction costs incurred during land exchanges may prevent agricultural land from being used (e.g. Kopeva et al., 1994; Vranken et al., 2004).

Policy factors

Agricultural policy, in terms of support price and subsidies, may result in land being left fallow. It may be compulsory for farmers to leave some arable land uncultivated, such as the case of set-aside requirements in the context of the Common Agricultural Policy (CAP) until 2008. Some studies have shown that farmers set aside land that is the least productive (e.g. Rygnestad and Fraser, 1996). Some complementary measures such as rotational set-aside were introduced to limit such practice (e.g. Guyomard et al., 1996). Set aside may also be not compulsory but possible for farmers to leave land uncultivated and still receive public money. This is for example the case of the CAP post-2003 reform: farmers may receive Single Farm Payments (SFP) even for unused land, providing that it is kept in Good Agricultural and Environmental Condition (GAEC). Breen et al., (2005), Bougherara and Latruffe (2007), Douarin et al. (2007), Latruffe and Davidova (2007) have, for example, investigated farmers' and landowners' intentions to take land out of production to keep it in GAEC. The opposite effect may be observed under different policies. For example, in the United States Goodwin and Mishra (2006) have shown that AMTA (Agricultural Market Transition Act) payments imply less land being left fallow. Price support may also determine farmers' acreage decisions; for example, Schoney (1995) reports that price stabilization programs influence Canadian farmers' fallow decisions.

3. Kosovo background and data set

Kosovo is a small country with total area of 1.1 million ha, out of which 53% is agricultural land. It has high density of population and as a result a small agricultural land area per inhabitant (0.24 ha), and a small arable area per household (Riinvest, 2005). Following the privatisation of the socially-owned enterprises, 86% of agricultural land is privately owned and is operated by family farms; the remaining is still under the ownership of producer cooperatives (1%) and socially-owned enterprises (13%) (UNMIK, 2003).

Agriculture accounts for 25% of GDP and between 25 and 35% of employment (World Bank and SOK, 2007). Nearly 60% of total population live in rural areas. GDP per capita is relatively low, EUR 1,200. According to the World Bank estimate (World Bank and SOK, 2007) the level of unemployment is around 30% of the labour force. Despite its typical rural character, the country is strongly dependent on imports of agricultural commodities and processed food. Lingard (2003) argues that one of the main reasons for this situation is that agriculture is stagnating as most of the farms produce for self-consumption. Latruffe et al. (2008) indicate that on average the share of agricultural output sold is only 13.5%, whilst the share of output used for household consumption is 38.1%. They argue that the main barriers to commercialisation are the imperfections in land and labour markets.

Family (household) farms in Kosovo are small. The definition of 'small' varies according to different authors (Hazel et al., 2007). Some commentators argue that small farms are farms with less than 2 ha of arable area; others put an emphasis on factor and product market integration defining as 'small' farms those that depend mainly on household labour and have as a primary goal the production for household consumption. In this paper, as the focus is on

land utilisation, small is understood as measured in agricultural land. In the Kosovo Green Book (UNMIK 2003:8) it is argued that "most farms in Kosovo are run to provide subsistence for households that, more often than not, are extended families and comprise well over ten members. Individual farms are of widely differing sizes ranging from below 1 ha to over 25 ha. Average farm size is 2.2 ha divided into an average of eight plots. Eighty percent of farms are between 0.5 and 2 ha".

Similarly to Latruffe et al. (2008), the present study is based on the Agricultural Household Survey (2005) carried out by the Statistical Office of Kosovo (SOK) in November and December 2005.² The survey covers land farmed by agricultural households living and farming in rural areas³. The survey does not include land belonging to agricultural households in rural areas that are not farming or land belonging to agricultural households living in urban areas in Kosovo or abroad unless the land is rented out to rural farming households. Additionally, land belonging to co-operatives and socially-owned enterprises, thus not farmed by households, is not included in the survey. The applied definition of household is a union of persons that live together and pool their income. Kosovo still has the traditional large rural households where several generations live under the same roof, and share income and meals. Usually the decision-maker is the head of household.

The survey is based on a two-level stratified sample (SOK, 2006). The initial sample size comprised 4,446 agricultural households. The first level of stratification is by region in order to obtain region estimates and to ensure full geographical coverage. The second level of stratification is by farm size to ensure representation of agricultural households. Once a village was chosen to be in the survey, the agricultural households in the village were stratified into three size categories (using land under cultivation as the value for stratification): 0-1.5 ha, 1.51-3.0 ha, and greater than 3 ha. After stratification, households were randomly selected for interviewing (SOK, 2006). To reduce the heterogeneity of the sample frame, and thus improve the estimates, all farms that were beyond the normal distribution, in terms of farm size or numbers of livestock, were identified and enumerated fully. These are referred to as 'large and specialized farms', and treated separately. They are not included in the present analysis.⁴

Land use was recorded plot by plot, including kitchen gardens. The survey also recorded plots left fallow for the production season (2005/2006), and the respondents (usually the heads of household) were asked to identify the reasons for the fallow land from a pre-determined list with an open option to specify a reason not included in the list. The responses concerning farmers' perception of barriers to cultivate all their land area are summarized in Chart 1. The majority of respondents (30.6%) emphasise the low economic profitability of farming as one of the reasons behind their decision. The lack of equipment and lack of manpower came as a second and third main reason. This indicates that farmers identify economic factors (low profit from farming and costly access to inputs) as their main constraints to utilisation of agricultural land. Farmers gave a lower priority to reasons such as general insecurity, danger due to possible land mines left from the military conflict, lack of other inputs than equipment and manpower, intentional crop rotation.

² The survey benefited from technical support of the project 'Agricultural Statistics and Policy Analysis Unit for Kosovo' (ASPAUK) funded by the EU EAR.

³ At least one member of the agricultural household should be working in farming.

⁴ For example, the threshold for large and specialised farms was 50 ha cereals, 10 ha potatoes, 4 ha vineyards, 3 ha field vegetables etc.

For the present study, the survey data was cleaned and 2,010 usable records were analysed.⁵ Out of these 2,010 households, 322 had some land left fallow for the coming production year. The descriptive statistics of some variables used in the analysis are presented in Table 1.

The minimum size of zero concerning the arable land is due to the fact that some households may have other type of utilised land, for example orchards, vineyards or pastures, but those were classified in different categories. The sample used in the present study confirms what was previously mentioned, i.e. farms in Kosovo are small when measured in land area, they are operated by large extended households (on average 9.4 members) and the share of output sold is low – around 9%. This illustrates the semi-subsistence character of farm households. During the previous season, on average, the sample households had left 6% of their land fallow.

4. Modeling the fallow decision

Determinants of fallowing decision of Kosovo's farm households are investigated using three different econometric modeling procedures that possibly fit the shape of the data distribution. The classic Tobit model is firstly used, and then results are compared with those of two other models addressing potential problems not accounted for in the Tobit model: a fractional response regression, and a zero-inflated binomial regression. All models were estimated accounting for endogeneity.

Dependent and explanatory variables

Instead of using binary models to explain why some farmers leave land fallow and others do not, as in most of the existing literature, here quantitative models are used to explain the determinants of the proportion of land left fallow. This enables to obtain deeper insights into the constraints faced by rural households in Kosovo. In all three models used here, the dependent variable of interest is the 'fallow share', reflecting the share of the total amount of land per farm left fallow in the reference production year 2005/06. Some farmers in the data set utilised all their land and consequently reported a zero fallow share. However, to avoid a likely selectivity bias with respect to estimation, the full sample is used and not just the sub-sample of farms that left some of their land fallow. Hence, by definition, the dependent variable is censored by 0 (i.e. total amount of land is utilised) and 1 (i.e. total amount of land is left fallow).

Based on the above literature review about the determinants of fallowing decisions, several explanatory variables are included in the three models. Human factors refer to the average age of the household members and the maximum number of years of education attained within the household. Proxies for economic factors include household size, total arable land, total land owned, total land rented, total area irrigated, share of the overall output sold, gross household income, and three dummies indicating what is the main farm output (dummies equal to 1 if more than half of the farm revenue is from grains, respectively fruits and vegetables, or forage). In order to capture other factors behind the decisions to leave land fallow, the reasons stated by the respondents for leaving land fallow (i.e. low economic profitability, lack of equipment, lack of manpower, lack of inputs, crop rotation, lack of security, mines, and other reasons) are included as well.

Some of the stated reasons might however be endogenously determined by: the prevailing soil and environmental conditions; the location of the farm and the plots; the infrastructure; the

⁵ The authors are grateful to Yann Desjeux who cleaned the initial Agricultural Household Survey dataset and reformatted some variables.

socioeconomic characteristics of the farmer and the household; the social interaction with peer-group members and opinion leaders. For these reasons, exogenous determinants must be used as instruments. Table 2 summarises such potential exogenous determinants for the different stated factors.

Model 1 - Instrumental variable Tobit regression

As explained above, the dependent variable's distribution is censored on the left at 0 and on the right at 1. Thus, a Tobit model is appropriate. To take into account the possible endogeneity problems with respect to some of the stated reasons for the fallow decision, an instrumental variable Tobit regression is used (Maddala, 1991; Greene, 2003). Formally,

$$y_{1i}^* = y_{2i}\beta + x_{1i}\gamma + u_i \quad [1]$$

$$y_{2i} = x_{1i}\Pi_1 + x_{2i}\Pi_2 + v_i \quad [2]$$

where $i = 1, \dots, N$ with N as the number of farms, y_{2i} is a $(1 \times p)$ vector of endogenous variables, x_{1i} is a $(1 \times k_1)$ vector of exogenous variables, x_{2i} is a $(1 \times k_2)$ vector of additional instruments, and the equation for y_{2i} is written in reduced form. By assumption, the error terms u_i and v_i are randomly normally distributed with zero means. β and γ are vectors of structural parameters, and Π_1 and Π_2 are matrices of reduced-form parameters. The latent variable y_{1i}^* is not observed, instead, we observe

$$\begin{cases} y_{1i}^* = 0 & \text{if } y_{1i} \leq 0 \\ y_{1i}^* = y_{1i} & \text{if } 0 < y_{1i} < 1 \\ y_{1i}^* = 1 & \text{if } y_{1i} \geq 1 \end{cases} \quad [3]$$

where y_{1i} is the share of land left fallow, the vector y_{2i} refers to the stated reasons for leaving land fallow that are endogenous (see Table 2), the vector x_{1i} refers to the other stated reasons and additional explanatory variables, and the vector x_{2i} refers to instruments (see Table 2). The exogeneity of the instruments used was tested by considering a Wald test formula. The model was estimated by using an efficient full maximum likelihood technique based on the likelihood function outlined in Greene (2003).

Model 2 - Fractional response regression

The dependent variable being the share of land left fallow, it is based on proportional data censored by 0 and 1. As Maddala (1991) observes, such data are not observationally censored but rather are defined only over the interval $[0,1]$. Hence, the censored normal regression model (Model 1 above) is conceptually flawed for proportional data and might result in misleading and biased estimates. Rather, the conditional mean must be a nonlinear function of the regressors, and heteroscedasticity could be a problem (Lin and Schmidt, 1984; Cook et al., 2008). Here the procedure follows Papke and Wooldridge (1996, 2008) who propose the assumption of a functional form for the dependent variable that imposes the desired constraints on the conditional mean of the dependent variable, namely

$$E(y|x) = G(x\theta) \quad [4]$$

where $G(\cdot)$ is a known nonlinear function satisfying $0 < G(\cdot) < 1$. The most obvious choice for $G(\cdot)$ is the logistic function which must be estimated using nonlinear techniques. The fractional response model to be estimated would follow the one outlined by [1] above and be

$$E\left[y_{1i}^* \mid (y_{2i}\beta + x_{1i}\gamma)\right] = G[(y_{2i}\beta + x_{1i}\gamma)\theta] \quad [5]$$

A quasi-maximum likelihood (QML) estimation procedure is used based on the Bernoulli log-likelihood function given by

$$LL_i(\theta) = y_{1i}^* \log[G((y_{2i}\beta + x_{1i}\gamma)\theta)] + (1 - y_{1i}^*) \log[1 - G((y_{2i}\beta + x_{1i}\gamma)\theta)] \quad [6]$$

The corresponding QML estimator of θ is defined by (Wagner, 2001)

$$\hat{\theta} \equiv \arg \max_{\theta} \sum_{i=1}^N LL_i(\theta) \quad [7]$$

To account for the possible endogeneity of some of the stated reasons for the fallow decision, in a first stage a multivariate probit is estimated (Maddala, 1991; Greene, 2003). Hence, the following M -equation multivariate probit model is considered

$$\begin{cases} y_{im}^* = \beta_m' x_{i1m} + \gamma_m' x_{i2m} + \varepsilon_{im} \\ y_{im} = 1 \text{ if } 0 < y_{im}^* < 1 \\ y_{im} = 0 \text{ otherwise} \end{cases} \quad [8]$$

where $m = 1, \dots, M$ with M the number of stated reasons, ε_{im} are error terms distributed as multivariate normal, each with a mean of zero, and a variance-covariance matrix V , where V has values of 1 on the leading diagonal and correlations $\rho_{jk} = \rho_{kj}$ as off-diagonal elements. The $(M \times N)$ vector of dependent variables y_{im} refers to the stated reasons for leaving land fallow. x_{1i} refers to the same exogenous variables and x_{2i} are the same instruments as in Model 1. The model is estimated by using a simulated maximum likelihood technique based on the likelihood function outlined in Cappellari and Jenkins (2003). The estimates obtained by the multivariate probit model are then used as the vector y_{2i} in [5].⁶

Model 3 - Zero-inflated binomial regression

The distribution of the dependent variable ‘fallow share’ is skewed to the left and contains a large proportion of zeros (i.e. excess zeros), namely 84%. To address this, a zero-inflated negative binomial regression model (ZINB) is applied which is a modified Poisson regression model and accounts for unobserved individual heterogeneity as a reason for such overdispersion in the data set. Lambert (1992) introduced the following zero-inflated Poisson (ZIP) model

$$\begin{cases} y_i \sim 0 & \text{with probability } q_i \\ y_i \sim \text{Poisson}(\lambda_i) & \text{with probability } 1 - q_i \quad (y_i = 0, 1, 2, 3, \dots) \end{cases} \quad [9]$$

$$\text{where } q_i = \frac{e^{z_i\gamma}}{1 + e^{z_i\gamma}}.$$

The individual farms are divided into farms which use all land for production (i.e. fallow share = 0) with probability q_i , and farms that potentially set a proportion of their land aside with probability $1 - q_i$. The unobservable probability q_i is generated as a logistic function of the observable covariates to ensure nonnegativity. Following Greene (2003) the observed

⁶ Because of limited space the estimates for the multivariate probit are not reported here.

variable y_i - here ‘fallow share’ - is generated as a product of the two latent variables z_i and y_i^* , such as

$$y_i = z_i y_i^* \quad [10]$$

where z_i is a binary variable with values 0 or 1 and y_i has a negative binomial (NB) distribution. Then,

$$\begin{cases} \Pr(y_i = 0) = \Pr(z_i = 0) + \Pr(z_i = 1, y_i^* = 0) = q_i + (1 - q_i)f(0) \\ \Pr(y_i = k) = (1 - q_i)f(k) \quad k = 1, 2, \dots \end{cases} \quad [11]$$

where $f(\cdot)$ is the negative binomial probability distribution for y_i^* . The binary process z_i is modeled as a logit specification using a constant-only specification for the inflation part whereas the likelihood function is given in Greene (2003). The Vuong non-nested test can be used to choose the best model specification, following

$$V = \frac{\sqrt{N\tilde{m}}}{s_m} \quad [12]$$

where $m_i = \ln[\hat{P}_1(y_i|x_i)/\hat{P}_2(y_i|x_i)]$ and $\hat{P}_1(y_i|x_i)$ and $\hat{P}_2(y_i|x_i)$ are the predicted probabilities of the two competing models with \tilde{m} as the mean, s_m as the standard deviation, and V following an asymptotically normal distribution. To account for the possible endogeneity of some of the stated factors for the fallow decision, in a first stage a multivariate probit is again estimated following the specification outlined above by [8].

5. Results and discussion

The results of the three estimated models are presented in Tables 3, 4 and 5 respectively. According to the different diagnosis tests performed, all estimated model specifications show a statistical significance at a satisfactory level and no severe signs of misspecification.

The results provide several insights into the determinants of the decision to leave some land fallow in Kosovo. First, regarding the reasons stated by the farmers, four of them have a significant impact on the fallowing decision in all three models: lack of inputs, lack of manpower, lack of equipment, lack of profitability. The three other reasons – namely crop rotation, mines and lack of security – are not identified as significant factors behind the decisions to leave land fallow. This does not fully confirm Chart 1, where lack of inputs was not a common reason among respondents while lack of security was more important, indicating that survey qualitative (yes/no) answers do not clearly relate to farmers’ decisions regarding the share of land left fallow. Second, regarding the other explanatory variables, the three models reveal that only the total arable land area, total land owned and the dummy for the farm specialisation in fruit and vegetables are significant determinants of the share of fallow land.

Results thus suggest that economic factors are the main determinants of fallowland in Kosovo. Farmers’ perceptions that agriculture is a low profit activity and their difficulty to access inputs are the major constraints to full land utilisation. Difficulties in obtaining production factors are revealed by the reasons stated by the respondents, as well as by the positive and significant effect of total land owned and the non-significant impact of the total land rented in all models. Farmers may own land that is inappropriate for them (it may be remote, fragmented, etc) and would need to exchange it on the land market. However, the

high transaction costs to participate in the rental market may be an important reason for leaving land fallow. This corroborates with Kostov and Lingard (2004) and Mathijs and Noev (2004) who argue that transactions costs are one of the main problems faced by subsistence farmers in Central and Eastern Europe. A larger farm arable area decreases the share of land left fallow in all three models. Larger arable areas are easier to cultivate using machinery, own or rented, particularly in cases when these areas are not split into many plots allocated in different places. In addition, often arable land means lowland and more fertile land with better returns. Finally, specialisation, namely fruit and vegetables, has a positive and significant impact on the fallow share, may be in relation to the fact that such production is labour intensive and is thus affected by the lack of inputs.

6. Conclusions

Understanding the factors behind the decision to leave land unused has always been of great interest to policy-makers, in particular in countries with a high dependency on food imports and where agricultural households are poor. While the bulk of the studies have concentrated on developing countries, very few papers deal with the issue in countries in transition from a centrally planned to a market system. In this context, however, it is not rare to have land left unutilised or even abandoned. This is still the case of Kosovo, a region that has been not only affected by privatisation of the land of socially-owned enterprises, but also by ethnic conflicts. In this paper, the factors behind the fallowing decisions in Kosovo were investigated by three econometric models run on household-level data. Differently to previous studies investigating only the binary decision to leave or not land fallow, here the share of land left fallow was used as the dependent variable. All three models, Tobit, a fractional response regression and a zero-inflated binomial regression (all accounting for endogeneity), produced statistical significance at a satisfactory level and did not show severe signs of misspecification. The results were robust and several determinants of the share of land left fallow were identified by all three models. The main factors for leaving land fallow indicated by the models is the lack of input and equipment on farms in Kosovo. This problem is recurrent in transition countries, in particular due to a limited access to credit (e.g. Davis and Gaburici 1999; Swinnen and Gow 1999; Petrick, 2004; Latruffe et al., 2008), and has been known to the policy-makers in Kosovo. In the Green Book (UNMIK, 2003) it is pointed out that in the mid-term the target population for support should be subsistence and semi-subsistence farms, and the necessary incentives for these farms might include some tax concessions on inputs and equipment.

Another important finding of the econometric analysis is that larger arable areas decrease the probability for fallow land. Smaller non-arable land areas, and in particular when skilled labor input and specialised equipment are necessary, for example fruit and vegetables, are more likely to bring fallow plots. One of the main stated factors for the decision to leave land fallow was the low profitability of farming. The increase in incentives to farmers by improving market institutions up- and downstream is one measure which can improve profitability and decrease the impediments to land use. During the period of typical productivist approach to farming in Western Europe, there were various (sometimes quite drastic) legal penalties for under-use of agricultural land - ranging from monetary penalties and compulsory leasing of under-utilised land to a third party, to the most controversial compulsory purchase of the land based on the principle of social obligation of ownership (Carty, 1977). However, this will really be counter-productive in Kosovo where the Government introduced process of privatisation of land of socially-owned enterprises is still underway. What could be done is to support the process of land consolidation which will

allow organising larger arable land parcels. Some preparations for institutional development in this direction have been reported with a plan for a new law on land consolidation (ISMAFRD, 2008).

Table 1: Descriptive statistics of the household sample used

	<i>Mean</i>	<i>Standard deviation</i>	<i>Minimum</i>	<i>Maximum</i>
Total arable area (ha)	1.41	2.41	0	62.0
Share of area owned (%)	93.78	18.66	0	100
Area under grains (ha)	0.94	2.10	0	61.1
Area under fruit and vegetables (ha)	0.18	0.55	0	11.2
Area under forage (ha)	1.01	1.29	0	13.8
Share of land left fallow	0.06	0.16	0	1.00
Number of household members	9.37	5.46	1	71
Share of output sold (%)	8.95	20.67	0	100
Gross household income (Euro)	1,003	3,053.66	0	53,550

Table 2: Exogenous determinants for the stated reasons to leave land fallow

<i>Stated reason for the fallow share</i>	<i>Exogenous determinants (i.e. instruments)</i>
Crop rotation	soil type and quality, plot altitude, environmental factors such as e.g. average precipitation
Mines	location of the farm/plot: e.g. border region to Macedonia, border region to Serbia, border region to Albania, main municipality, location near major road axis
Lack of security	location of the farm/plot: e.g. border region to Macedonia, border region to Serbia, border region to Albania, main municipality, location near major road axis
Other reasons	peer-group effects (proxy: average fallow share in village, average fallow share in municipality), transaction costs for participation in input or output markets

Table 3: Results from the instrumental variable Tobit model

(N = 2,010)	coefficient ¹	t-value
<i>Dependent variable: share of fallow land</i>
